Abstract (arXiv)

The future 100-km circular collider FCC at CERN is planned to operate in one of its modes as an electron-positron FCC-ee machine. We give an overview of the theoretical status compared to the experimental demands of one of four foreseen FCC-ee operating stages, which is Z-boson resonance energy physics. FCC-ee Tera-Z stage for short. The FCC-ee Tera-Z will deliver the highest integrated luminosities as well as very small systematic errors for a study the Standard Model (SM) with unprecedented precision. In fact, the FCC-ee Tera-Z will allow to study at least one more guantum field theoretical perturbative order compared to the LEP/SLC precision. The real problem is that the present precision of theoretical calculations of the various observables within the SM does not match that of the anticipated experimental measurements. The bottle-neck problems are specified. In particular, the issues of precise QED unfolding and of the correct calculation of SM pseudo-observables are critically reviewed. In an Executive Summary we specify which basic theoretical calculations are needed to meet the strong experimental expectations at the FCC-ee Tera-Z. Several methods, techniques and tools needed for higher order multi-loop calculations are presented. By inspection of the Z-boson partial and total decay widths analysis, arguments are given that at the beginning of operation of the FCC-ee Tera-Z, the theory predictions may be tuned to be precise enough not to limit the physics interpretation of the measurements. This statement is based on the anticipated progress in analytical and numerical calculations of multi-loop and multi-scale Feynman integrals and on the completion of two-loop electroweak radiative corrections to the SM pseudo-observables this year. However, the above statement is conditional as the theoretical issues demand a very dedicated and focused investment by the community.

50 years of the Z-boson theory (1967)

VOLUME 19, NUMBER 21

PHYSICAL

PHYSICAL REVIEW LETTERS

20 NOVEMBER 1967

S. Weinberg

"A MODEL OF LEPTONS"

$$\begin{split} \varphi_1 &\equiv (\varphi^0 + \varphi^{0\dagger} - 2\lambda)/\sqrt{2} \quad \varphi_2 &\equiv (\varphi^0 - \varphi^{0\dagger})/i\sqrt{2} \,. \end{split} {(5)} \\ \text{The condition that } \varphi_1 \text{ have zero vacuum expec-} \end{split}$$

tation value to all orders of perturbation theory tells us that $\lambda^{2} \le M_{1}^{2}/2k$, and therefore the field φ_{1} has mass M_{1} while φ_{2} and φ^{-} have mass zero. But we can easily see that the Goldstone bosons represented by φ_{2} and φ^{-} have no physical coupling. The Lagrangian is gauge invariant, so we can perform a combined isospin and hypercharge gauge transformation which eliminates φ^{-} and φ_{2} everywhere⁶ without changing anything else. We will see that C_{ϕ} is very small, and in any case M_{1} might be very large,⁷ so the φ_{1} couplings will also be disregarded in the following.

The effect of all this is just to replace φ everywhere by its vacuum expectation value

$$=\lambda \begin{pmatrix} 1\\ 0 \end{pmatrix}$$
. (6)

The first four terms in $\ensuremath{\mathfrak{L}}$ remain intact, while the rest of the Lagrangian becomes

$$-\frac{1}{9}\lambda^2 g^2 [(A_{\mu}^{-1})^2 + (A_{\mu}^{-2})^2] \\ -\frac{1}{9}\lambda^2 (gA_{\mu}^{-3} + g'B_{\mu})^2 - \lambda G_e \overline{e}e.$$
(7)

We see immediately that the electron mass is λG_{e} . The charged spin-1 field is

$$W_{\mu} \equiv 2^{-1/2} (A_{\mu}^{1} + i A_{\mu}^{2}) \qquad (8$$

and has mass

 $M_{W} = \frac{1}{2} \lambda g$. (9)

The neutral spin-1 fields of definite mass are

$$Z_{\mu} = (g^{2} + g'^{2})^{-1/2} (gA_{\mu}^{3} + g'B_{\mu}), \qquad (10)$$

$$A_{\mu} = (g^2 + g'^2)^{-1/2} (-g'A_{\mu}^3 + gB_{\mu}). \tag{11}$$

Their masses are

$$M_{Z} = \frac{1}{2} \lambda (g^{2} + g'^{2})^{1/2}, \qquad (12)$$

 $M_{A} = 0,$

(13)

so A_{μ} is to be identified as the photon field. The interaction between leptons and spin-1 mesons is

$$\frac{\frac{18}{2\sqrt{2}}}{2\sqrt{2}}\overline{e}\gamma^{\mu}(1+\gamma_{5})^{\nu}W_{\mu}^{\mu} + \text{H.c.} + \frac{\frac{182}{(g^{2}+g^{\prime \prime})^{1/2}}\overline{e}\gamma^{\mu}eA_{\mu} \\ + \frac{i(g^{2}+g^{\prime \prime})^{1/2}}{4}\Big[\Big(\frac{3}{g^{\prime \prime 2}+g^{\prime 2}}\Big)\overline{e}\gamma^{\mu}e-\overline{e}\gamma^{\mu}\gamma_{5}e+\overline{\nu}\gamma^{\mu}(1+\gamma_{5})^{\mu}\Big]Z_{\mu}.$$

over large number of EWPOs

Table 10.5: Principal Z pole observables and their SM predictions (cf. Table 10.4). The first π_{ℓ}^{2} is the effective weak mixing angle extracted from the hadronic charge asymmetry, the second is the combined value from the Tevatron [164–166], and the third from the LHC [170–172]. The values of A_{ℓ} are (i) from $A_{\ell R}$ for hadronic final states [159]; (ii) from $A_{\ell R}$ for leptonic final states and from polarized Bhabba scattering [161]; and (iii) from the angular distribution of the τ polarization at LEP 1. The A_{τ} values are from SLD and the total τ polarization, respectively.

Updates for error estimations

• Theory error estimate is not well defined, ideally $\Delta_{th} \ll \Delta_{exp}$

- Common methods: Count prefactors (α , N_c , N_f , ...)
 - Extrapolation of perturbative series
 - Renormalization scale dependence
 - Renormalization scheme dependence

• Also parametric error from external inputs (m_t , m_b , α_s , $\Delta \alpha_{had}$, ...)

see, Ayres Freitas: 1604.00406

Crucial issue: accuracy of calculations

For 2-loops we maintained 4 digits for EWPOs.

A calculation of the radiative corrections $\delta_1 \div \delta_4$ and $\delta'_1 \div \delta'_3$ with a 10% accuracy (corresponding to two significant digits) should suffice to meet future experimental demands.

Minimal precision of 3-loop EW calculations:

- Calculating N^3LO with 10% accuracy (two digits), we can replace intrinsic error estimation $\delta\Gamma_Z = \sqrt{\sum_{i=1}^5 \delta_i^2} \sim 0.4$ MeV by $\delta\Gamma_Z = \sqrt{\sum_{i=1}^5 (\delta_i/10)^2} \sim 0.04$ MeV.
- The requirement of FCC-ee^{*exper. error*} $(\Gamma_Z) \sim 0.1$ MeV can be met and the condition

$$\delta$$
[FCCee^{theor.}(Γ_Z)] ~ 0.04 MeV < δ [FCCee^{exper.}(Γ_Z)] ~ 0.1 MeV

will be fullfilled.

Estimations for total values of missing EWPOs

| | $\delta\Gamma_Z \; [\text{MeV}]$ | $\delta R_l \ [10^{-4}]$ | $\delta R_b \ [10^{-5}]$ | $\sin^2\theta_{\rm eff}^{\rm l} \left[10^{-5}\right]$ | $\sin^2\theta_{\rm eff}^{\rm b} \left[10^{-5}\right]$ | $\sigma_{ m had}^0~[{ m pb}]$ |
|-----------|----------------------------------|--------------------------|--------------------------|---|---|-------------------------------|
| EXP-FCCee | 0.1 | $2 \div 20$ | $2 \div 6$ | 6 | 70 | 4 |
| TH1* | 0.4 | 60 | 10 | 4.5 | 5 | 6 |
| TH2* | 0.15 | 60 | 5 | 1.5 | $1.5 \div 2$ | 6 |

- TH1 estimates from geometric series (3-loops)
- TH2 estimates from prefactor scaling (beyond 3-loops)
- * 10% knowledge (2 digits) of the error would decrease numbers by factor 10

And this should be the goal for future $\geq N^3 LO$ calculations

Conclusions on Z-lineshape and EWPOs for next years - theory

- NNLO EWPOs completed;
- Strong demand from FCC-ee to the theory on precision;
- Future \geq NNNLO calculations must be done with at least 10% accuracy, e.g. $\mathcal{O}(\alpha \alpha_s^2)$, $\mathcal{O}(N_f \alpha^2 \alpha_s)$, $\mathcal{O}(N_f^2 \alpha^3)$, $\mathcal{O}(N_f^{\leq 1} \alpha^3)$, $\mathcal{O}(\alpha^3 \alpha_s)$, $\mathcal{O}(\alpha^2 \alpha_s^2)$;
- We have tools for that;
- To be on the safe side, we would like to have at least 2 independent calculations;
- Still, a lot work is ahead, for success and efficiency, we need steady progress in numerical and also (semi)analytical approaches in multiloop calculations

BACKUP SLIDES

Discussion of NNNLO accuracy

Two factors play role:

- Number of diagrams
- Their complexity

Goal: at least 2-digits accuracy for EWPOs.

We estimate it to be possible, even from present perspective.

2-loops \longrightarrow 3-loops

$$m_1 = M_t, m_2 = M_W$$

The integrals contain up to three dimensionless parameters

$$\left\{\frac{M_{H}^{2}}{M_{Z}^{2}}, \frac{M_{W}^{2}}{M_{Z}^{2}}, \frac{m_{t}^{2}}{M_{Z}^{2}}, \frac{(M_{Z}+i\varepsilon)^{2}}{M_{Z}^{2}}\right\}$$

2-loops \longrightarrow 3-loops

• The standard model prediction for the effective weak mixing angle can be written as

$$\sin^2 \theta_{\rm eff}^{\rm b} = \left(1 - \frac{M_W^2}{M_Z^2}\right) \left(1 + \Delta \kappa_{\rm b}\right)$$

• The bosonic electroweak two-loop corrections amount to

$$\Delta \kappa_{\rm b}^{(\alpha^2,{\rm bos})} = -0.9855 \times 10^{-4}$$

DFGRU, Phys.Lett. B762 (2016) 184

| | Order | Value $[10^{-4}]$ | Order | Value $[10^{-4}]$ |
|---------------------------------|-----------------------|-------------------|-----------------------|-------------------|
| | α | 468.945 | $\alpha_t^2 \alpha_s$ | 1.362 |
| | $\alpha \alpha_s$ | -42.655 | α_t^3 | 0.123 |
| | $\alpha_{\rm ferm}^2$ | 3.866 | $\alpha_t \alpha_s^2$ | -7.074 |
| $\pm 0.001 -! \longrightarrow$ | $\alpha_{\rm bos}^2$ | -0.9855 | $\alpha_t \alpha_s^3$ | -1.196 |

Table: Comparison of different orders of radiative corrections to $\Delta \kappa_{\rm b}$. Input Parameters: M_Z , Γ_Z , M_W , Γ_W , M_H , m_t , α_s and $\Delta \alpha$

- one-loop contributions [Akhundov, Bardin, Riemann, 1986] [Beenakker, Hollik, 1988]
- two-loop fermionic contributions [Awramik, Czakon, Freitas, Kniehl, 2009]
- two-loop bosonic contributions [Dubovyk, Freitas, JG, Riemann, Usovitsch, 2016]

Partial higher-order corrections

```
\begin{array}{l} \mathcal{O}(\alpha_t \alpha_s^2) \\ \mathcal{O}(\alpha_t \alpha_s^3) \\ \mathcal{O}(\alpha^2 \alpha_t) \text{ and } \mathcal{O}(\alpha_t^3) \end{array}
```

Avdeev: 1994, Chetyrkin: 1995

Schroder: 2005, Chetyrkin: 2006, Boughezal: 2006 vanderBij: 2000, Faisst: 2003

3-loops. Basic bookkeeping

| $Z ightarrow b ar{b}$ | | | |
|------------------------|--------|--|---|
| Number of | 1 loop | 2 loops | 3 loops |
| topologies | 1 | $14 \rightarrow^{(\mathbf{A})} 7 \rightarrow^{(\mathbf{B})} 5$ | $211 \rightarrow^{(\mathbf{A})} 84 \rightarrow^{(\mathbf{B})} 50$ |
| Number of diagrams | 15 | $2383 \rightarrow^{(\mathbf{A},\mathbf{B})} 1114$ | $490387 \rightarrow^{(\mathbf{A},\mathbf{B})} 120187$ |
| Fermionic loops | 0 | 150 | 17580 |
| Bosonic loops | 15 | <mark>964</mark> | 102607 |
| Planar diagrams | 1T/15D | 4T/981D | 35T/84059D |
| Non-planar diagrams | 0 | 1T/133D | 15T/36128D |

Table: Some statistical overview for $Z \rightarrow b\bar{b}$ multiloop studies. At 3 loops there are in total almost half a million of diagrams present. After basic refinements (A) and (B) about 10^5 genuine 3-loop vertex diagrams remain. In (A) tadpoles and products of lower loops are excluded, in (B) symmetries of topologies are taken into account.

A complete zoo of heavy particles m_t, m_W, m_Z, m_H @NNNLO level

MB: ϵ^{0} [8-dim], $1/\epsilon$ [7-dim]; SD: ϵ^{0} [8-dim], $1/\epsilon$ [7-dim];

At 2-loops up to three dimensionless parameters (all 4 at 3-loops):

$$\left\{\frac{M_{H}^{2}}{M_{Z}^{2}}, \frac{M_{W}^{2}}{M_{Z}^{2}}, \frac{m_{t}^{2}}{M_{Z}^{2}}, \frac{(M_{Z}+i\varepsilon)^{2}}{M_{Z}^{2}}\right\}$$

Sector decomposition

FIESTA 3 [A.V.Smirnov, 2014], SecDec 3 [Borowka, et. al., 2015] and pySecDec [Borowka, et. al., 2017]

Mellin-Barnes integral approach

- With AMBRE 2 [Gluza, et. al., 2011] (AMBRE 3 [Dubovyk, et. al., 2015]) we derive Mellin-Barnes representations for planar (non-planar) topologies. One may use PlanarityTest [Bielas, et. al, 2013] for automatic identification.
- Expansion in terms of $\epsilon = (4 D)/2$ is done with MB [Czakon, 2006], MBresolve [A. Smirnov, V. Smirnov, 2009], barnesroutines (D. Kosower).
- For the numerical treatment of massive Mellin-Barnes integrals with Minkowskian regions, the package MBnumerics is being developed since 2015.
